Native Computing and Optimization

Hang Liu
December 4th, 2013
Overview

• Why run native?
• What is a native application?
• Building a native application
• Running a native application

• Setting affinity and pinning tasks
• Optimization
  – Vectorization
  – Alignment
  – Parallelization
What is a native application?

- It is an application built to run exclusively on the MIC coprocessor.
- MIC is not binary compatible with the host processor
  - Instruction set is similar to Pentium, but not all 64 bit scalar extensions are included.
  - MIC has 512 bit vector extensions, but does NOT have MMX, SSE, or AVX extensions.
- Native applications can’t be used on the host CPU, and vice versa.
Why run a native application?

• It is possible to login and run applications on the MIC without any host intervention

• Easy way to get acquainted with the properties of the MIC
  – Performance studies
  – Single card scaling tests (OMP/MPI)
  – No issues with data exchange with host

• The native code probably performs quite well on the host CPU once you build a host version
  – Good path for symmetric runs (afternoon talk)
Will My Code Run on Xeon Phi?

• Yes

• … but that’s the wrong question
  – Will your code run *best* on Phi?, or
  – Will you get great Phi performance without additional work?
Building a native application

- Cross-compile on the host (login or compute nodes)
  - No compilers installed on coprocessors
- MIC is fully supported by the Intel C/C++ and Fortran compilers (v13+):
  
  ```
  icc  -openmp -mmic mysource.c  -o myapp.mic
  ifort -openmp -mmic mysource.f90  -o myapp.mic
  ```
- The `-mmic` flag causes the compiler to generate a native mic executable
- It is convenient to use a `.mic` extension to differentiate MIC executables
Running a native application

• Options to run from mic0 from a compute node:
  1. Traditional ssh remote command execution
     • `c422-703% ssh mic0 ls`
     • Clumsy if environment variables or directory changes needed
  2. Interactively login to mic:
     • `c422-703% ssh mic0`
     • Then use as a normal server
  3. Explicit launcher:
     • `c422-703% micrun ./a.out.mic`
  4. Implicit launcher:
     • `c422-703% ./a.out.mic`
Native Application Launcher

• The micrun launcher has three nice features:
  – It propagates the current working directory
  – It propagates the shell environment (with translation)
    • Environment variables that need to be different on host and coprocessor need to be defined using the MIC_ prefix on the host. E.g.,
      – c422-703% export MIC_OMP_NUMTHREADS=183
      – c422-703% export MIC_KMP_AFFINITY="verbose,balanced"
  – It propagates the command return code back to the host shell
• These features work whether the launcher is used explicitly or implicitly
Environmental Variables on the MIC

• If you ssh to mic0 and run directly from the card use the regular names:
  – OMP_NUM_THREADS
  – KMP_AFFINITY
  – I_MPI_PIN_PROCESSOR_LIST
  – ...

• If you use the launcher, use the MIC_ prefix to define them on the host:
  – MIC_OMP_NUM_THREADS
  – MIC_KMP_AFFINITY
  – MIC_I_MPI_PIN_PROCESSOR_LIST
  – ...

• You can also define a different prefix:
  – export MIC_ENV_PREFIX=MYMIC
  – MYMIC_OMP_NUM_THREADS
  – ...
Native Execution Quirks

- The mic runs a lightweight version of Linux, based on BusyBox
  - Some tools are missing: `w`, `numactl`
  - Some tools have reduced functionality: `ps`

- Relatively few libraries have been ported to the coprocessor environment

- The implicit or explicit launcher approach makes it convenient to use MIC on Stampede
Best Practices For Running Native Apps

- Always bind processes to cores
  - For MPI tasks (more on next presentation)
    - `I_MPI_PIN`
    - `I_MPI_PIN_MODE`
    - `I_MPI_PIN_PROCESSOR_LIST`
  - For threads
    - `KMP_AFFINITY={compact, scatter, balanced}`
    - `KMP_AFFINITY=explicit,proclist=[0,1,2,3,4]`
    - Adding `verbose` will dump the full affinity information when the run starts
    - Adding `granularity=fine` binds to specific thread contexts and may help in codes with heavy L1 cache reuse
- The MIC is a single chip, so there is no need for `numactl`
- If other affinity options can’t be used the command `taskset` is available.
KMP_AFFINITY Example

- **compact**
  - 1 2 3 4
  - 5 6 7 8

- **balanced**
  - 1 2
  - 3 4
  - 5 6
  - 7 8

- **scatter**
  - 1 5
  - 2 6
  - 3 7
  - 4 8
Logical to Physical Processor Mapping

- **Hardware:**
  - Physical Cores are 0..60
  - Logical Cores are 0..243

- **Mapping is not what you are used to!**
  - Logical Core 0 maps to Physical core 60, thread context 0
  - Logical Core 1 maps to Physical core 0, thread context 0
  - Logical Core 2 maps to Physical core 0, thread context 1
  - Logical Core 3 maps to Physical core 0, thread context 2
  - Logical Core 4 maps to Physical core 0, thread context 3
  - Logical Core 5 maps to Physical core 1, thread context 0
  - Logical Core 240 maps to Physical core 59, thread context 3
  - Logical Core 241 maps to Physical core 60, thread context 1
  - Logical Core 242 maps to Physical core 60, thread context 2
  - Logical Core 243 maps to Physical core 60, thread context 3

- **OpenMP threads start binding to logical core 1, not logical core 0**
  - For compact mapping 240 OpenMP threads are mapped to the first 60 cores
    - No contention for the core containing logical core 0 – the core that the O/S uses most
  - But for scatter and balanced mappings, contention for logical core 0 begins at 61 threads
    - Not much performance impact unless O/S is very busy
    - Best to avoid core 60 for offload jobs & MPI jobs with compute/communication overlap
How Do I Tune Native Applications?

• Vectorization and Parallelization are critical!
  – Single-thread scalar performance: ~1 GHz Pentium

• Vector width is 512 bits
  – 8 double precision values / 16 single precision values
  – You don’t want to lose factors of 8-16 in performance

• Compiler reports provide important information about effectiveness of compiler at vectorization
  – Start with a simple code – the compiler reports can be very long & hard to follow
  – There are lots of options & reports! Details at:
Vectorization Compiler reports

- Option `-vec-report3` gives diagnostic information about every loop, including
  - Loops successfully vectorized (also at `-vec-report1`)
  - Loops not vectorized & reasons (also at `-vec-report2`)
  - Specific dependency info for failures to vectorize
- Option `-vec-report6` provides additional info:
  - Array alignment for each loop
  - Unrolling depth for each loop

- Quirks
  - Functions typically have most/all of the vectorization messages repeated with the line number of the call site – ignore these and look at the messages with the line number of the actual loop
  - Reported reasons for not vectorizing are not very helpful – look at specific dependency info
• Code: STREAM Copy kernel
  
  ```c
  #pragma omp parallel for
  for (j=0; j<STREAM_ARRAY_SIZE; j++)
      c[j] = a[j];
  ```

• vec-report messages
  - stream_5-10.c(354): (col. 6) remark: vectorization support: reference c has aligned access.
  - stream_5-10.c(354): (col. 6) remark: vectorization support: reference a has aligned access.
  - stream_5-10.c(354): (col. 6) remark: vectorization support: streaming store was generated for c.
  - stream_5-10.c(353): (col. 2) remark: LOOP WAS VECTORIZED.
  - stream_5-10.c(354): (col. 6) remark: vectorization support: reference c has unaligned access.
  - stream_5-10.c(354): (col. 6) remark: vectorization support: reference a has unaligned access.
  - stream_5-10.c(354): (col. 6) remark: vectorization support: unaligned access used inside loop body.
  - stream_5-10.c(353): (col. 2) remark: loop was not vectorized: vectorization possible but seems inefficient.

• Many other combinations of messages are possible
  - Remember that OpenMP will split loops in ways that can break 64-Byte alignment – alignment depends on thread count
Additional Compiler Reports

- Option `--opt-report-phase hpo` provides good info on OpenMP parallelization
- Option `--opt-report-phase hlo` provides info on software prefetching
- Option `--opt-report 1` gives a medium level of detail from all compiler phases, split up by routine
- Option `--opt-report-file=filename` saves the lengthy optimization report output to a file
Tuning Limitations

• Currently there is no support for `gprof` when compiling native applications
• Profiling is supported by Intel’s `Vtune` product
  – But this is not currently enabled on Stampede
  – Vtune is a complex profiling software that deserves its own training session
Performance Tuning Notes (1)

- Xeon Phi always has multi-threading enabled
  - Four thread contexts per physical core
  - Registers are replicated
  - L1D, L1I, and (private, unified) L2 caches are shared

- Instruction issue limitation:
  - A core can issue 1-2 instructions per cycle (only 1 can be a vector instruction)
  - L1D Cache can deliver 64 Bytes (1 vector register) every cycle
  - But a thread can only issue a instructions every other cycle
  - Need at least two threads to fully utilize the vector unit
  - Using 3-4 threads does not increase maximum issue rate, but often helps tolerate latency
Performance Tuning Notes (2)

• Cache Hierarchy:
  – L1I and L1D are 32kB, 8-way associative, 64-Byte cache lines
    • Same sizes & associativity as Xeon E5 (“Sandy Bridge”), but *shared* when using multiple threads/core
    • 1 cycle latency for scalar loads, 3 cycles for vector loads
  – L2 (unified, private) is 512kB, 8-way associative, 64-Byte lines
    • Latency ~25 cycles (idle), increases under load
    • Bandwidth is 1 cache line every other cycle
  – On an L2 cache miss: check directories to see if data in another L2 cache
    • Clean or Dirty data will be transferred to requestor’s L1D
    • This eliminates load from DRAM on shared data accesses
    • Cache-to-Cache transfers are about 275ns, independent of relative core numbers
Performance Tuning Notes (3)

- For a load request, a delay occurs when
  - fetching the data from L2 if it is not in L1
  - fetching the data from memory if it is not in L2
  - idle memory latency ~ 270ns

- Hardware Prefetch
  - No L1 prefetchers
  - Simplified L2 prefetcher
    - Only identifies strides up to 2 cache lines
    - Prefetches up to 4 cache-line-pairs per stream
    - Monitors up to 16 streams (on different 4kB pages)
      - These are *shared* by the hardware threads on a core

- Software prefetch is often required to obtain good bandwidth
Prefetch and Bandwidth

Effect of HW & SW Prefetch on STREAM Triad Bandwidth on Xeon Phi

- 61 threads
- 122 threads
- 183 threads
- 244 threads

STREAM Triad BW (MB/s)

Categorization:
- No HW PF, No SW PF
- No HW PF, SW PF O3
- No HW PF, SW PF Opt
- With HW PF, No SW PF
- With HW PF, SW PF O3
- With HW PF, SW PF Opt
Software Prefetch vs Data Location

• Xeon Phi can only issue one vector instruction every other cycle from a single thread context, so:
  – If data is already in the L1 Cache, Vector Prefetch instructions use up valuable instruction issue bandwidth
  – But, if data is in the L2 cache or memory, Vector Prefetch instructions provide significant increases in sustained performance.

• The next slide shows the effect of including vector prefetch instructions (default with “-O3”) vs excluding them (with “-no-opt-prefetch”)
  – Data is L1 contained for array sizes of 2k elements or less
  – Data is L2-contained for array sizes of ~32k elements or less
Effect of SW Prefetch with Data on Cache

Stream2 DAXPY on Xeon Phi SE10P: Effect of Software Prefetch on Performance with Data in Cache

Number of 64-bit elements per array

Sustained Bandwidth (MB/s)
Tuning Memory Bandwidth on the MIC

- STREAM Benchmark performance varies considerably with compilation options
  - “-O3” flags, small pages, malloc: 63 GB/s to 98 GB/s
  - “-O3” flags, small pages, -fno-alias: 125 GB/s to 140 GB/s
  - “tuned” flags, small pages: 142 GB/s to 162 GB/s
  - “tuned” flags, large pages: up to 175 GB/s
- Best Performance can be obtained with 1, 2, 3, or 4 threads per core
  - Aggressive SW prefetch or >4 memory access streams per thread gives best results with 1 thread per core
  - Less aggressive SW prefetch or 1-4 memory access streams per thread give better results with more threads
- Details:
  - “-O3” compiler flags: -O3 -openmp -mcmodel=medium -fno-alias
  - “tuned” compiler flags use “-O3” flags plus:
    -mP2OPT_hlo_use_const_pref_dist=64 \-mP2OPT_hlo_use_const_second_pref_dist=32 \-mGLOB_default_function_attrs="knc_stream_store_controls=2"
Intel reference material

- Main Software Developers web page:
- A list of links to very good training material at:
- Many answers can also be found in the Intel forums:
- Specific information about building and running “native” applications:
- Debugging:
More Intel reference Material

- Search for these at www.intel.com by document number
  - This is more likely to get the most recent version than searching for the document number via Google.

- Primary Reference:
  - “Intel Xeon Phi Coprocessor System Software Developers Guide” (document 488596 or 328207)

- Advanced Topics:
  - “Intel Xeon Phi Coprocessor Instruction Set Architecture Reference Manual” (document 327364)
  - “Intel Xeon Phi Coprocessor (codename: Knights Corner) Performance Monitoring Units” (document 327357)

- WARNING:
  - Intel sometimes describes the number of vector registers as 16 in this documents. The actual number is 32.
Questions?
